**It is recommended that you spend about 30 minutes on this question.**

**2** The properties of many magnetic materials are affected by temperature. One effect is the loss of permanent magnetism when the temperature of a magnetic material exceeds a particular value. This temperature is known as the Curie point.

Design an experiment to investigate how the magnetic field strength of a magnet depends on the temperature of the magnet in the range from 0 °C to 200 °C.

In your account you should pay particular attention to

**(a)** the method of measuring the magnetic field strength (magnetic flux density),

**(b)** how the temperature of the magnet would be measured in the given range,

**(c)** the method of ensuring that the temperature of the magnet is uniform,

**(d)** the procedure to be followed,

**(e)** the control of variables.
